

Large Super-TF Bearings

A revolutionary combination of longer service life and superior resistance against wear, seizure and heat.

Outstanding toughness, performance and economy — NSK technology sets a new standard for long service life

Outstanding Performance

NSK's Large Super-TF Bearings have been especially designed for outstanding toughness under harsh conditions of use, where they surpass even NSK's TF Bearings. Incorporating new materials and new heat treatment technology, they combine long service life under contaminated lubrication with good resistance to wear, seizure and heat. In comparison with bearings made of conventional materials, Super-TF Bearings offer

- 10 times the service life with contaminated lubrication,
- twice the service life under clean lubrication,
- less than one-third the rate of wear and a 40% improvement in seizure resistance,
- dimensional stability superior to that of JIS (Japanese Industrial Standards) SUJ2 bearing steel or ASTM 52100 bearing steel, and
- improved heat resistance, giving 4 times the service life at 160°C.

Applications of Large Super-TF Bearings

Large Super-TF Bearings are ideally suited to a wide range of applications requiring long service life under contaminated lubrication conditions. Super-TF technology can be applied to a wide range of bearing types, including cylindrical and tapered roller bearings, spherical roller bearings, deep-groove ball bearings, and angular-contact ball bearings. One representative application is four-row tapered roller bearings for roll-neck bearings in steel or aluminum rolling mills, where they are subject to scale entry and heavy loads.

Large Super-TF Bearings and TF Technology

In its quest for longer bearing service life, NSK has spent many years analyzing the mechanisms of fatigue in bearings under various conditions, and researching and developing materials and heat treatment processes. The range of approaches to achieving longer service life taken by our research team are shown in Fig. 1. The technology incorporated in our Large Super-TF Bearings is designed to maximize service life under conditions where bearings are subject to surface-originating flaking.

Fig. 1 Approaches to achieving longer service life in bearings

The Development of Super-TF Bearings

The problem: Contaminated lubrication conditions

Bearings may be required to operate under clean or dirty conditions; under dirty conditions their lubricating oil is easily contaminated. Metal particles or casting sand in the lubricating oil make dents in the contact surfaces. As shown in Fig. 2, stress is concentrated around these dents and eventually leads to cracking and to surface-originating flaking. The concentration of stress around a dent is expressed by the equation $[P/P_0 \propto (r/c)^{-0.24}]$, where “r” is the radius at the shoulder of the dent and “2c” is the shoulder-to-shoulder width of the dent. The greater the value of “r/c”, the smaller the stress concentration and the longer the service life of the bearing.

The solution: TF technology

NSK is a world leader in the research and development of material properties to reduce the concentration of stress around surface dents. As shown in Fig. 3, our work has revealed that a high level of retained austenite is an extremely effective means of maximizing the r/c value around surface dents in the bearing material. TF technology is a unique heat treatment process developed by NSK to optimize the level of retained austenite in bearing materials. It is the basic technology incorporated in Super-TF Bearings and is patented in the United States of America (USP4904094) and Germany (DE3922720C2).

Material Properties of Large Super-TF Bearings

As we have seen, the approach to achieving long service life taken in NSK’s Super-TF Bearings is to minimize the concentration of stress around the shoulders of surface dents. A high level of retained austenite helps to maximize the value of r/c and reduce the concentration of stress around dents. However, austenite itself has a soft structure and reduces the hardness of the bearing material. In order to meet the seemingly conflicting needs for greater hardness of the bearing material and a higher level of

Fig. 2 Concentration of stress around a surface dent

Fig. 3 Relationship of r/c value to retained austenite level

retained austenite, we decided to adopt a technique that would promote the uniform distribution and reduce the diameter of carbide and carbonitride particles in the bearing material. To this end, our researchers developed a new type of steel named SAC2, containing appropriate quantities of chrome and molybdenum, which are used in the formation of carbides and nitrides, and have developed new carburization and carbonitriding heat treatment techniques that form finer carbide and carbonitride particles. NSK holds some 10 patents regarding these techniques in Japan and overseas, including two in the United States of America, USP4871268 and USP5137375.

Fig. 4 shows the surface structure of a Large Super-TF Bearing with the even distribution of fine carbide and carbonitride particles obtained with the new material and heat treatment. For comparison, Fig. 5 shows the surface of an ordinary carburized steel bearing. Fig. 6 and 7 show the results of image analysis of Figs. 4 and 5. From Fig. 6, it is clear that the Large Super-TF Bearing has more and finer carbide and carbonitride particles. Fig. 8 shows that the formation of finer carbide and carbonitride particles gives Super-TF Bearings greater hardness and higher retained austenite levels than TF Bearings. As a result, Large Super-TF Bearings achieve a high r/c value (Fig. 9).

Characteristics of Large Super-TF Bearings

Large Super-TF Bearings not only achieve longer service life under contaminated lubrication, but also offer higher resistance against peeling, wear, seizure and heat. In addition, they also achieve outstanding cost performance.

Service life under contaminated lubrication conditions

Table 1 and Fig. 10 show the results of service life tests conducted under contaminated lubrication conditions with NSK L44649/10 tapered roller bearings. If the service life (L_{10}) of an ordinary carburized steel bearing of this type is taken as 1, then the life of TF and Super-TF Bearings will be respectively 4.5 and 10.2 (Table 1). NSK's Large Super-TF Bearings thus offer over ten times the service life of ordinary carburized steel bearings. Service life is generally affected both by the conditions in which the bearing is used and by the amount of contamination in the lubricant. Under harsh conditions, service life may fall to as little as 1/5 of the catalog life. Large Super-TF Bearings for the first time assure a service life under contaminated lubrication that exceeds the catalog life of existing products (Fig. 11).

Table 1 Comparison of service life of L44649/10 tapered roller bearings

Bearing material	Ordinary carburized steel	TF	Super-TF
Life ratio	1	4.5	10.2

Wear and seizure resistance

Besides extending service life under contaminated lubrication conditions, another goal is to increase the bearing's resistance to wear and seizure by ensuring the dispersion of a large number of fine carbides and nitrides in the bearing material. Fig. 12 presents the results of a Sawin-type wear test, showing the degree of wear and the seizure limit for different types of bearing material. The test reveals that Large Super-TF Bearings have superior wear resistance to both SUJ2 steel and TF Bearings. Super-TF Bearings are also 40% more resistant seizure than both SUJ2 steel and TF Bearings.

Fig. 11 Comparison of service life under contaminated lubrication

Fig. 12 Comparison of wear resistance

Service life under boundary lubrication conditions

Under boundary lubrication conditions where there is insufficient EHL film, metal surfaces come into direct contact, reducing bearing life. Fig. 13 shows the results of service life tests conducted under conditions where oil film parameter L , which represents the ratio of the thickness of the oil film to the roughness of the surface, is very small ($L=0.3$). When L is very small, peeling damage occurs (Fig. 14), but in Super-TF material, the concentration of stress around the projections of the contact area is reduced, giving a service life approximately 5.5 times that of ordinary carburized steel bearings.

Heat resistance

Fig. 15 shows the results of service life tests conducted with 6206 ball bearings at 160°C under clean lubricating conditions. The results of the test reveal that Super-TF Bearings (heat-resistant specifications) have approximately 4 times the service life of SUJ2X26 steel bearings.
